- Setting: No labeled data, but knowledge source that may limit or bias classifier choices
- As knowledge increases, how well does reduction in entropy of label distribution predict performance? How precise does the knowledge need to be?
- Evaluate other effects of constrained parameter space: stability, convergence, label assignment

- For a given input x , prior knowledge constrains choice of label y ; if we view as distribution $p(y | x)$, $H(Y | X)$ is one measure of task difficulty
- No labeled data required; but note we compare different types of knowledge, fixed model type
- Fano's equality (Fano, 1961): Conditional entropy part of lower bound on $p(\text{Error})$

- Label entropy is reasonable indicator of performance with different knowledge sets; and no labeled data is required
- Even simple constraints can have big benefits for accuracy, training stability & convergence
- Uncertainty is of course not the only factor in accuracy. For future work: more complete predictive measures
